CS 161 (Stanford, Winter 2024) Section 7

1 Warm-up: Greedy or Not?

Sometimes it can be tricky to tell when a greedy algorithm applies. For each problem, say whether or not the greedy solution would work for the problem. If it wouldn't work, give a counter example.

1. You have unlimited objects of different sizes, and you want to completely fill a box with as few objects as possible, or output that it is impossible. (Greedy: Keep putting the largest object possible in for the space you have left)
2. You have unlimited objects of size 3^k for every k, and you want to completely fill a box with as few objects as possible. (Greedy: same approach as the previous problem)
3. You have lines that can fit a fixed number of characters. You want to print out a series of words in a given order while using as few lines as possible. (Greedy: Fit as many words as you can on a given line)
4. There are n hotels in a line, each distance 1 apart and hotel i costing h_i dollars to stay at. You can travel at most distance k every day. Find the minimum total cost of hotels you need to stop at. (Greedy: Go as far as you can before stopping at a hotel)

2 Encoding

Suppose we encode lowercase letters into a numeric string as follows: we encode a as 1, b as 2, ..., and z as 26. Given a numeric string S of length n, develop an $O(n)$ algorithm to find how many letter strings this can correspond to. For example, for the numeric string 123, the algorithm should output 3 because the letter strings that map to this numeric string are abc, lc, and aw.

3 Knight Moves

Given an 8×8 chessboard and a knight that starts at position $a1$, devise an algorithm that returns how many ways the knight can end up at position xy after k moves. Knights move ± 1 squares in one direction and ± 2 squares in the other direction. In other words, knights move in a pattern similar to a "L".

Note: on a chessboard, rows are labeled from 1-8 and columns are labeled from $a - h$.

4 Rod Cutting

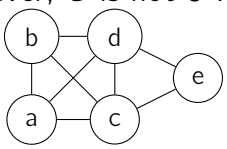
Suppose we have a rod of length k, where k is a positive integer. We would like to cut the rod into integer-length segments such that we maximize the *product* of the resulting segments' lengths. Multiple cuts may be made. For example, if $k = 8$, the maximum product is 18 from cutting the rod into three pieces of length $3, 3$, and 2. Write an algorithm to determine the maximum product for a rod of length k.

5 Well Connected Graphs

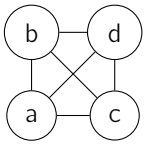
Let $G = (V, E)$ be an undirected, unweighted graph. For a subset $S \subseteq V$, define the **subgraph induced by** S to be the graph $G' = (S, E')$, where $E' \subseteq E$, and an edge $\{u, v\} \in E$ is included in E' if and only if $u \in S$ and $v \in S$.

For any $k < n$, say that a graph G is k-well-connected if every vertex has degree at least k. (That is, if there are least k edges coming out of each vertex).

For example, in the graph G below, the subgraph G' induced by $S = \{a, b, c, d\}$ is shown on the right. G' is 3-well-connected, since every vertex in G' has degree at least 3. However, G is not 3-well-connected since vertex E has degree 2.



$G = (V, E)$



$G' = (S, E')$, for $S = \{a, b, c, d\}$

Observation: If G' is a k-well-connected subgraph induced by S, and $v \in V$ has degree $< k$, then $v \notin S$. This is because v would have degree $< k$ in the induced subgraph G' as well, and so G' couldn't be k-well-connected if it included v.

Guided by the **observation** above, design a greedy algorithm to find a maximal set $S \subseteq V$ so that the subgraph $G' = (S, E')$ induced by S is k-well-connected. You do not need to formally prove why your algorithm is correct, but give an informal but convincing justification.

In the example above, if $k = 3$, your algorithm should return $\{a, b, c, d\}$, and if $k = 4$ your algorithm should return the empty set.

You may assume that your representation of a graph supports the following operations:

- `degree(v)`: return the degree of a vertex in time $O(1)$
- `remove(v)`: remove a vertex and all edges connected to that vertex from the graph, in time $O(\text{degree}(v))$.

Your algorithm should run in time $O(n^2)$.

6 Cutting Ropes

Suppose we are given n ropes of different lengths, and we want to tie these ropes into a single rope. The cost to connect two ropes is equal to sum of their lengths. We want to connect all the ropes with the minimum cost.

For example, suppose we have 4 ropes of lengths $7, 3, 5$, and 1. One (not optimal!) solution would be to combine the 7 and 3 rope for a rope of size 10, then combine this new size 10 rope with the size 5 rope for a rope of size 15, then combine the rope of size 15 with the rope of size 1 for a final rope of size 16. The total cost would be $10 + 15 + 16 = 41$. (Note: the optimal cost for this problem is 29. How might you combine the ropes for that cost?)

Find a greedy algorithm for the minimum cost and prove the correctness of your algorithm.

7 Mice to Holes

There are n mice and n holes along a line. Each hole can accommodate only 1 mouse. A mouse can stay at his position, move one step right from x to $x+1$, or move one step left from x to $x-1$. Any of these moves consumes 1 minute. Mice can move simultaneously. Assign mice to holes such that the time it takes for the last mouse to get to a hole is minimized, and return the amount of time it takes for that last mouse to get to its hole.

Example:

Mice positions: $[4, -4, 2]$

Hole positions: $[4, 0, 5]$

Best case: the last mouse gets to its hole in 4 minutes. $\{4 \to 4, -4 \to 0, 2 \to 5\}$ and $\{4 \to 5, -4 \to 0, 2 \to 4\}$ are both possible solutions.
