

# Lecture 8

## Hashing

# Announcements

- There will not be new HW posted this week, because it's time to study for the...

# Midterm!

- Wednesday, Feb 11, 6-9pm!
- Stay tuned for logistics email
- Covers up through last week (Lecture 7)

- Students with course conflicts:

Email staff as soon as possible

[cs161-staff-win2526@cs.stanford.edu](mailto:cs161-staff-win2526@cs.stanford.edu)

# How to study for the midterm?

- Go over lecture + homework + **section** + textbook
- DO PRACTICE PROBLEMS.
  - Algorithms Illuminated, CLRS have great problems!
  - Practice exam(s)
- Office Hours!
  - Most effective if you come with specific questions/topics
  - Note: some OH have moved earlier in the week
- Friday, here, 1:30-2:50: midterm review session

# Outline

- **Hash tables** are another sort of data structure that allows fast **INSERT/DELETE/SEARCH**.
  - like self-balancing binary trees
  - The difference is we can get better performance in expectation by using randomness.
- **Hash families** are the magic behind hash tables.
- **Universal hash families** are even more magical.

# Goal

- We want to store nodes with keys in a data structure that supports fast **INSERT/DELETE/SEARCH**.

- **INSERT** 
- **DELETE** 
- **SEARCH** 

# Last time

- Self balancing trees:
  - $O(\log(n))$  deterministic INSERT/DELETE/SEARCH

# Today:

- Hash tables:
  - $O(1)$  expected time INSERT/DELETE/SEARCH
- Worse worst-case performance, but often great in practice.

eg, Python's `dict`, Java's `HashSet/HashMap`, C++'s `unordered_map`  
Hash tables are used for databases, caching, object representation, ...

# One way to get $O(1)$ time

This is called  
“direct addressing”

- Say all keys are in the set  $\{1, 2, 3, 4, 5, 6, 7, 8, 9\}$ .

• INSERT: 

• DELETE: 

• SEARCH: 

# Problem

*The universe is  
really big!*

- If the keys may come from a “universe”

$U = \{1, 2, \dots, 10000000000\}$ , direct addressing  
takes a lot of space.

# Solution?

Put things in buckets based on one digit

INSERT:

Now **SEARCH**

It's in this bucket somewhere...  
go through until we find it.

Problem

INSERT:

Now SEARCH

22

....this hasn't made  
our lives easier...

# Hash tables

- That was an example of a hash table.
  - not a very good one, though.
- We will be **more clever** (and less deterministic) about our bucketing.
- This will result in fast (expected time) INSERT/DELETE/SEARCH.

# But first! Terminology.

- $U$  is a *universe* of size  $M$ .
  - $M$  is really big.
- But only a few (at most  $n$ ) elements of  $U$  are ever going to show up.
  - $M$  is waaaaayyyyyyy bigger than  $n$ .
- But we don't know which ones will show up in advance.

Only a  $n$  keys will ever show up.

Example:  $U$  is the set of all strings of at most 280 ascii characters. ( $128^{280}$  of them).

The only ones which I care about are those which appear as trending hashtags on twitter. [#hashinghashtags](#)

*There are way fewer than  $128^{280}$  of these.*

# Hash Functions

- A hash function  $h: U \rightarrow \{1, \dots, n\}$  is a function that maps elements of  $U$  to buckets  $1, \dots, n$ .

- **Note!** For this lecture,  $n$  is **both** #buckets and #(things that might show up).
- That doesn't need to be the case, but in general we should think of those two things as being on the same order.

# Hash Tables (with chaining)

A **hash table** consists of:

- An array of  $n$  buckets.
- Each bucket stores a linked list.
  - We can insert into a linked list in time  $O(1)$
  - To find something in the linked list takes time  $O(\text{length}(\text{list}))$ .
- A hash function  $h: U \rightarrow \{1, \dots, n\}$ .
  - For example,  $h(x) = \text{least significant digit of } x$ .

INSERT:

# Hash Tables (with chaining)

A **hash table** consists of:

- An array of  $n$  buckets.
- Each bucket stores a linked list.
  - We can insert into a linked list in time  $O(1)$
  - To find something in the linked list takes time  $O(\text{length}(\text{list}))$ .
- A hash function  $h: U \rightarrow \{1, \dots, n\}$ .
  - For example,  $h(x) = \text{least significant digit of } x$ .

**For demonstration purposes only!**  
This is a terrible hash function! Don't use this!

INSERT:

SEARCH 43:

Scan through all the elements in bucket  $h(43) = 3$ .

DELETE 43:

Search for 43 and remove it.

## Aside: Hash tables with open addressing

- The previous slide is about hash tables with chaining.
- There's also something called "open addressing"
- You don't need to know about it for this class.

\end{Aside}

# Hash Tables (with chaining)

A **hash table** consists of:

- Array of  $n$  buckets.
- Each bucket stores a linked list.
  - We can insert into a linked list in time  $O(1)$
  - To find something in the linked list takes time  $O(\text{length}(\text{list}))$ .
- A hash function  $h: U \rightarrow \{1, \dots, n\}$ .
  - For example,  $h(x) = \text{least significant digit of } x$ .

**For demonstration purposes only!**

INSERT:

SEARCH 43:

Scan through all the elements in bucket  $h(43) = 3$ .

DELETE 43:

Search for 43 and remove it.

# Outline

- **Hash tables** are another sort of data structure that allows fast **INSERT/DELETE/SEARCH**.
  - (We still need to figure out how to do the bucketing)

**Interlude:** motivation for hash families.

- **Hash families** are the magic behind hash tables.
- **Universal hash families** are even more magical.

# What we want from a hash table

1. We want there to be not many buckets (say,  $n$ ).
  - This means we don't use too much space
2. We want the items to be pretty spread-out in the buckets.
  - This means it will be fast to SEARCH/INSERT/DELETE

vs.

# Worst-case analysis

- Goal: Design a function  $h: U \rightarrow \{1, \dots, n\}$  so that:
  - No matter what  $n$  items of  $U$  a bad guy chooses, the buckets will be balanced.
  - Here, balanced means  $O(1)$  entries per bucket.
- If we had this\*, then we'd achieve our dream of  $O(1)$   
**INSERT/DELETE/SEARCH**

So, does such a function exist?

This is impossible!

No deterministic hash function can defeat worst-case input!

# We really can't beat the bad guy here.

- The universe  $U$  has  $M$  items
- They get hashed into  $n$  buckets
- At least one bucket has at least  $M/n$  items hashed to it.
- $M$  is waayyyy bigger than  $n$ , so  $M/n$  is bigger than  $n$ .
- **Bad guy chooses  $n$  of the items that landed in this very full bucket.**

# Solution: Randomness

# The game

Plucky the pedantic penguin

What does  
**random** mean  
here? Uniformly  
random?

1. An adversary chooses any  $n$  items  $u_1, u_2, \dots, u_n \in U$ , and any sequence of INSERT/DELETE/SEARCH operations on those items.

INSERT 13, INSERT 22, INSERT 43,  
INSERT 92, INSERT 7, SEARCH 43,  
DELETE 92, SEARCH 7, INSERT 92

2. You, the algorithm, chooses a **random** hash function  $h: U \rightarrow \{1, \dots, n\}$ .

3. **HASH IT OUT** #hashpuns

# Example of a random hash function

- $h: U \rightarrow \{1, \dots, n\}$  is a **uniformly random function**.
  - That means that  **$h(1)$**  is a **uniformly random** number between 1 and  $n$ .
  - **$h(2)$**  is also a **uniformly random** number between 1 and  $n$ , independent of  $h(1)$ .
  - **$h(3)$**  is also a **uniformly random** number between 1 and  $n$ , independent of  $h(1)$ ,  $h(2)$ .
  - ...
  - **$h(M)$**  is also a **uniformly random** number between 1 and  $n$ , independent of  $h(1)$ ,  $h(2)$ , ...,  $h(M-1)$ .

# Randomness can help!

Intuitively: The bad guy can't foil a hash function that they don't yet know.

Lucky the  
Lackadaisical Lemur

Plucky the Pedantic  
Penguin

Why not? What if there's some strategy that foils a random function with high probability?

We'll need to do some analysis...

# Intuitive goal

It's **bad** if lots of items land in  $u_i$ 's bucket.  
So we want **not that**.

# Formal goal

We could replace “2” here with any constant; it would still be good. But “2” will be convenient.

- Let  $h$  be a random hash function.
- Want: For all ways a bad guy could choose  $u_1, u_2, \dots, u_n$  to put into the hash table, and for all  $i \in \{1, \dots, n\}$ ,  
$$E[\text{number of items in } u_i\text{'s bucket}] \leq 2.$$

- If that were the case\*:

- For each INSERT/DELETE/SEARCH operation involving  $u_i$ ,  
$$E[\text{time of operation}] = O(1)$$

This is what we wanted at the beginning of lecture!

\*Assuming  $h(u)$  takes  $O(1)$  time to compute

# Goal:

- Come up with a distribution on hash functions so that:
- For all  $i=1, \dots, n$ ,  
     $E[\text{number of items in } u_i\text{'s bucket}] \leq 2.$

# Aside

- For all  $i=1, \dots, n$ ,

$$E[\text{number of items in } u_i \text{'s bucket}] \leq 2.$$

vs

- For all  $i=1, \dots, n$ :

$$E[\text{number of items in bucket } i] \leq 2$$

Are these the same?

Think-Pair-Share Terrapins

No! (This was your pre-lecture exercise!)

# Aside

- For all  $i=1, \dots, n$ ,

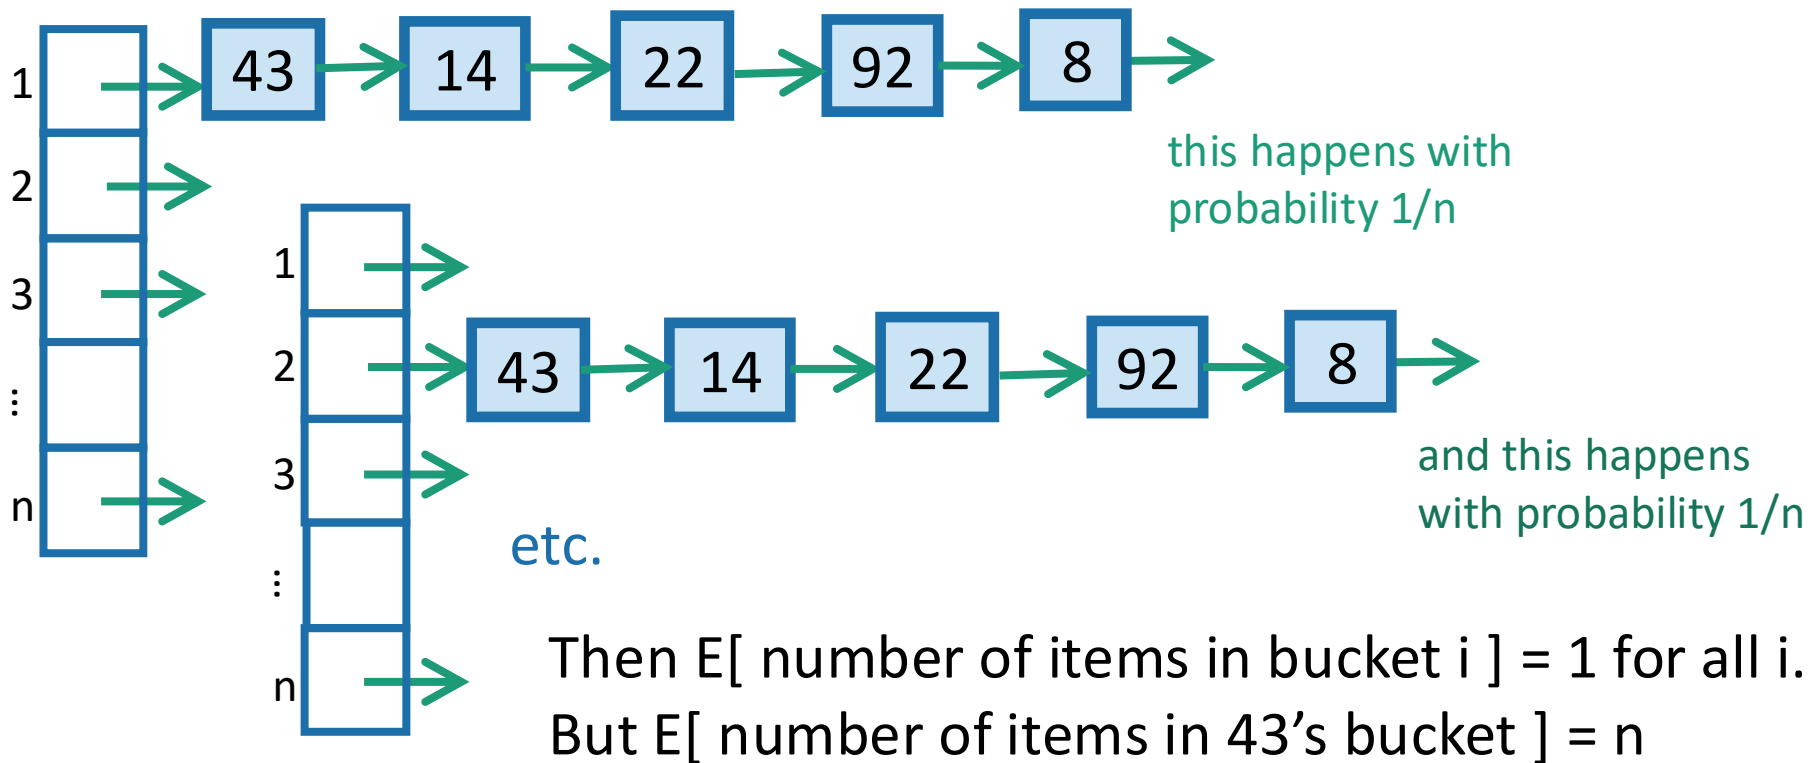

$$E[\text{number of items in } u_i \text{'s bucket}] \leq 2.$$

vs

- For all  $i=1, \dots, n$ :

$$E[\text{number of items in bucket } i] \leq 2$$

Suppose that:

# Goal:

- Come up with a distribution on hash functions so that:
- For all  $i = 1, \dots, n$ ,  
     $E[\text{number of items in } u_i\text{'s bucket}] \leq 2.$

# Claim:

- The goal is achieved by a uniformly random hash function.

# Proof of Claim

- Let  $h$  be a uniformly random hash function.
- Then for all  $i = 1, \dots, n$ ,  
 $E[\text{number of items in } u_i\text{'s bucket}] \leq 2$ .

- $E[\text{\# items in } u_i\text{'s bucket}] =$
- $= E[\sum_{j=1}^n \mathbf{1}\{h(u_i) = h(u_j)\}]$
- $= \sum_{j=1}^n P\{h(u_i) = h(u_j)\}$
- $= 1 + \sum_{j \neq i} P\{h(u_i) = h(u_j)\}$
- $= 1 + \sum_{j \neq i} 1/n$
- $= 1 + \frac{n-1}{n} \leq 2$ .

Exercise: show this formally!  
Intuitively, there are  $n$  possibilities where  $u_j$  can land, and only one of them is  $h(u_i)$ .

# A uniformly random hash function leads to balanced buckets

- We just showed:
  - For all ways a bad guy could choose  $u_1, u_2, \dots, u_n$ , to put into the hash table, and for all  $i \in \{1, \dots, n\}$ ,  
$$E[\text{number of items in } u_i \text{'s bucket}] \leq 2.$$
- Which implies\*:
  - No matter what sequence of operations and items the bad guy chooses,  
$$E[\text{time of INSERT/DELETE/SEARCH}] = O(1)$$
- So our solution is:

Pick a uniformly random hash function?

\*Assuming  $h(u)$  takes  $O(1)$  time to compute

# What's wrong with this plan?

- Hint: How would you implement (and store) and uniformly random function  $h: U \rightarrow \{1, \dots, n\}$ ?

Think-Pair-Share Terrapins  
1 minute think  
1 minute pair and share

- If  $h$  is a uniformly random function:
  - That means that  **$h(1)$**  is a **uniformly random** number between 1 and  $n$ .
  - **$h(2)$**  is also a **uniformly random** number between 1 and  $n$ , independent of  $h(1)$ .
  - **$h(3)$**  is also a **uniformly random** number between 1 and  $n$ , independent of  $h(1)$ ,  $h(2)$ .
  - ...
  - **$h(M)$**  is also a **uniformly random** number between 1 and  $n$ , independent of  $h(1)$ ,  $h(2)$ , ...,  $h(M-1)$ .

# A uniformly random hash function is not a good idea.

- In order to store/evaluate a uniformly random hash function, we'd use a lookup table:

x	h(x)
AAAAAA	1
AAAAAB	5
AAAAAC	3
AAAAAD	3
...	
ZZZZZY	7
ZZZZZZ	3

All of the M  
things in the  
universe

- Each value of  $h(x)$  takes  $\log(n)$  bits to store.
- Storing M such values requires  $M\log(n)$  bits.
- In contrast, direct addressing (initializing a bucket for every item in the universe) requires only M bits.

# Another way to say this

- There are lots of hash functions.
- There are  $n^M$  of them.
- Writing down a random one of them takes  $\log(n^M)$  bits, which is  $M \log(n)$ .

# Solution

- Pick from a smaller set of functions.

A cleverly chosen subset of functions. We call such a subset a **hash family**.

*We need only  $\log|H|$  bits to store an element of  $H$ .*

# Outline

- **Hash tables** are another sort of data structure that allows fast **INSERT/DELETE/SEARCH**.
  - like self-balancing binary trees
  - The difference is we can get better performance in expectation by using randomness.
- **Hash families** are the magic behind hash tables.
- **Universal hash families** are even more magic.

# Hash families

- A hash family is a collection of hash functions.

"All of the hash functions" is an example of a hash family.

# Example:

a smaller hash family

- $H = \{ \text{function which returns the least sig. digit,} \\ \text{function which returns the most sig. digit} \}$
- Pick  $h$  in  $H$  at random.
- Store just one bit to remember which we picked.

This is still a terrible idea!  
Don't use this example!  
For pedagogical purposes only!

# The game

$h_0$  = Most\_significant\_digit

$h_1$  = Least\_significant\_digit

$H = \{h_0, h_1\}$

1. An adversary (who knows  $H$ ) chooses any  $n$  items  $u_1, u_2, \dots, u_n \in U$ , and any sequence of INSERT/DELETE/SEARCH operations on those items.

2. You, the algorithm, chooses a **random** hash function  $h: U \rightarrow \{0, \dots, 9\}$ . Choose it randomly from  $H$ .

I picked  $h_1$

INSERT 19, INSERT 22, INSERT 42,  
INSERT 92, INSERT 0, SEARCH 42,  
DELETE 92, SEARCH 0, INSERT 92

## 3. HASH IT OUT #hashpuns

# This is not a very good hash family

- $H = \{ \text{function which returns least sig. digit,} \\ \text{function which returns most sig. digit} \}$
- On the previous slide, the adversary could have been a lot more adversarial...

# The game

$h_0$  = Most\_significant\_digit

$h_1$  = Least\_significant\_digit

$H = \{h_0, h_1\}$

1. An adversary (who knows  $H$ ) chooses any  $n$  items  $u_1, u_2, \dots, u_n \in U$ , and any sequence of INSERT/DELETE/SEARCH operations on those items.

2. You, the algorithm, chooses a **random** hash function  $h: U \rightarrow \{0, \dots, 9\}$ . Choose it randomly from  $H$ .

I picked  $h_0$

## 3. HASH IT OUT #hashpuns

101 11 121 141 131

# Outline

- **Hash tables** are another sort of data structure that allows fast **INSERT/DELETE/SEARCH**.
  - like self-balancing binary trees
  - The difference is we can get better performance in expectation by using randomness.
- **Hash families** are the magic behind hash tables.
- **Universal hash families** are even more magic.

# How to pick the hash family?

- Definitely not like in that example.
- Let's go back to that computation from earlier....

# Proof of Claim

- Let  $h$  be a uniformly random hash function.
- Then for all  $i = 1, \dots, n$ ,  
 $E[\text{number of items in } u_i\text{'s bucket}] \leq 2.$

$$\begin{aligned} & \bullet E[\text{\# items in } u_i\text{'s bucket}] = \\ & \bullet = E\left[\sum_{j=1}^n \mathbf{1}\{h(u_i) = h(u_j)\}\right] \\ & \bullet = \sum_{j=1}^n P\{h(u_i) = h(u_j)\} \\ & \bullet = 1 + \sum_{j \neq i} P\{h(u_i) = h(u_j)\} \\ & \bullet = 1 + \sum_{j \neq i} 1/n \\ & \bullet = 1 + \frac{n-1}{n} \leq 2. \end{aligned}$$

All that we needed  
was that this is  $1/n$

# Universal hash families

- $H$  is a **universal hash family** if, when  $h$  is chosen uniformly at random from  $H$ ,

$$\text{for all } u_i, u_j \in U \quad \text{with } u_i \neq u_j,$$
$$P_{h \in H} \{ h(u_i) = h(u_j) \} \leq \frac{1}{n}$$

- Earlier analysis shows: if we draw  $h$  uniformly at random from a universal hash family  $H$ , we will have expected time\*  $O(1)$  INSERT/DELETE/SEARCH!
- And if  $H$  is small, we can store a random  $h \in H$  efficiently!

# The whole scheme will be

Choose  $h$  randomly from  $H$

We can store  $h$  using  $\log|H|$  bits.

Universe  $U$

$h$

Probably these buckets will be pretty balanced.

# Universal hash families

- H is a ***universal hash family*** if, when h is chosen uniformly at random from H,

for all  $u_i, u_j \in U$  with  $u_i \neq u_j$ ,

$$P_{h \in H} \{ h(u_i) = h(u_j) \} \leq \frac{1}{n}$$

- **Universal hash family:** if you choose  $h$  randomly from  $H$ ,

# Example

$$\text{for all } u_i, u_j \in U \text{ with } u_i \neq u_j, \\ P_{h \in H} \{ h(u_i) = h(u_j) \} \leq \frac{1}{n}$$

- $H$  = the set of all functions  $h: U \rightarrow \{1, \dots, n\}$ 
  - We saw this earlier – it corresponds to picking a uniformly random hash function.
  - Unfortunately this  $H$  is really really large.

- **Universal hash family:** if you choose  $h$  randomly from  $H$ ,

$$\text{for all } u_i, u_j \in U \quad \text{with } u_i \neq u_j, \\ P_{h \in H} \{ h(u_i) = h(u_j) \} \leq \frac{1}{n}$$

# Non-example

- $h_0 = \text{Most\_significant\_digit}$
- $h_1 = \text{Least\_significant\_digit}$
- $H = \{h_0, h_1\}$

Prove that this choice of  $H$  is  
NOT a universal hash family!

2 minutes think

1 minute pair and share

- **Universal hash family:** if you choose  $h$  randomly from  $H$ ,

# Non-example

$$\text{for all } u_i, u_j \in U \text{ with } u_i \neq u_j, \\ P_{h \in H} \{ h(u_i) = h(u_j) \} \leq \frac{1}{n}$$

- $h_0 = \text{Most\_significant\_digit}$
- $h_1 = \text{Least\_significant\_digit}$
- $H = \{h_0, h_1\}$

NOT a universal hash family:

$$P_{h \in H} \{ h(101) = h(111) \} = 1 > \frac{1}{10}$$

# A small universal hash family??

- Here's one:

- Pick a prime  $p \geq M$ . (And not much bigger than  $M$ )
- Define

$$f_{a,b}(x) = ax + b \mod p$$

$$h_{a,b}(x) = f_{a,b}(x) \mod n$$

- Define:

$$H = \{ h_{a,b}(x) : a \in \{1, \dots, p-1\}, b \in \{0, \dots, p-1\} \}$$

# A small universal hash family??

- Here's one:

- Pick a prime  $p \geq M$ . (And not much bigger than  $M$ )
- Define

$$f_{a,b}(x) = ax + b \mod p$$

$$h_{a,b}(x) = f_{a,b}(x) \mod n$$

- Define:

$$H = \{ h_{a,b}(x) : a \in \{1, \dots, p-1\}, b \in \{0, \dots, p-1\} \}$$

- Claims:

$H$  is a universal hash family.

→ A random  $h \in H$  takes  $O(\log M)$  bits to store.

See CLRS (Thm 11.5) if you are curious, but you don't need to know why this is true for this class.

A random  $h \in H$  takes  $O(\log M)$  bits to store  
(And more!)

$$H = \{ h_{a,b}(x) : a \in \{1, \dots, p-1\}, b \in \{0, \dots, p-1\} \}$$

$$|H| = p \cdot (p-1) = O(M^2)$$

- Just need to store two numbers:
  - $a$  is in  $\{1, \dots, p-1\}$
  - $b$  is in  $\{0, \dots, p-1\}$
  - Store  $a$  and  $b$  with  $2\log(p)$  bits
  - By our choice of  $p$  (close to  $M$ ), that's  $O(\log(M))$  bits.
- Also, given  $a$  and  $b$ ,  $h$  is fast to evaluate!
  - It takes time  $O(1)$  to compute  $h(x)$ .
- Compare: direct addressing was  $M$  bits!
  - Example: If  $M = 128^{280}$ ,  $\log(M) = 1960$ .

# A small universal hash family??

- Here's one:

- Pick a prime  $p \geq M$ . (And not much bigger than  $M$ )
- Define

$$f_{a,b}(x) = ax + b \mod p$$

$$h_{a,b}(x) = f_{a,b}(x) \mod n$$

- Define:

$$H = \{ h_{a,b}(x) : a \in \{1, \dots, p-1\}, b \in \{0, \dots, p-1\} \}$$

- Claims:

$H$  is a universal hash family.

✓ A random  $h \in H$  takes  $O(\log M)$  bits to store.

See CLRS (Thm 11.5) if you are curious, but you don't need to know why this is true for this class.

$$H = \{ h_{a,b}(x) : a \in \{1, \dots, p-1\}, b \in \{0, \dots, p-1\} \}$$

So the whole scheme will be

Choose  $a$  and  $b$  at random  
and form the function  $h_{a,b}$

We can store  $h$  in space  
 $O(\log(M))$  since we just need  
to store  $a$  and  $b$ .

Universe U

$h_{a,b}$

$n$  buckets

Probably  
these  
buckets will  
be pretty  
balanced.

# Outline

- **Hash tables** are another sort of data structure that allows fast **INSERT/DELETE/SEARCH**.
  - like self-balancing binary trees
  - The difference is we can get better performance in expectation by using randomness.
- **Hash families** are the magic behind hash tables.
- **Universal hash families** are even more magic.

Recap 

Want  $O(1)$

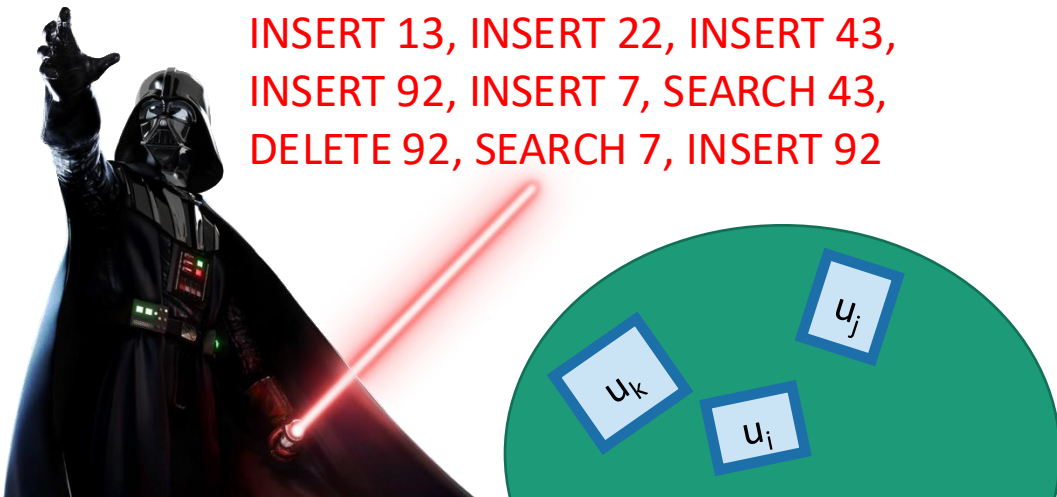

INSERT/DELETE/SEARCH

# We studied this game

1. An adversary chooses any  $n$  items  $u_1, u_2, \dots, u_n \in U$ , and any sequence of  $L$  INSERT/DELETE/SEARCH operations on those items.

INSERT 13, INSERT 22, INSERT 43,  
INSERT 92, INSERT 7, SEARCH 43,  
DELETE 92, SEARCH 7, INSERT 92

2. You, the algorithm, chooses a **random** hash function  $h: U \rightarrow \{1, \dots, n\}$ .

## 3. HASH IT OUT

# Uniformly random h was good

- If we choose h uniformly at random,

for all  $u_i, u_j \in U$  with  $u_i \neq u_j$ ,

$$P_{h \in H} \{ h(u_i) = h(u_j) \} \leq \frac{1}{n}$$

- That was enough to ensure that all INSERT/DELETE/SEARCH operations took  $O(1)$  time in expectation, even on adversarial inputs.

# Uniformly random $h$ was bad

- If we actually want to implement this, we have to store the hash function  $h$ .
- That takes a lot of space!
  - We may as well have just initialized a bucket for every single item in  $U$ .
- Instead, we chose a function randomly from a smaller set.

# Universal Hash Families

H is a universal hash family if:

- If we choose  $h$  uniformly at random in  $H$ ,  
for all  $u_i, u_j \in U$  with  $u_i \neq u_j$ ,  
$$P_{h \in H} \{ h(u_i) = h(u_j) \} \leq \frac{1}{n}$$

This was all we needed to make  
sure that the buckets were  
balanced in expectation!

- We gave an example of a really small universal hash family, of size  $O(M^2)$
- That means we need only  $O(\log M)$  bits to store it.

Hashing a universe of size  $M$  into  $n$  buckets, where at most  $n$  of the items in  $M$  ever show up.

# Conclusion:

- We can build a hash table that supports **INSERT/DELETE/SEARCH** in  $O(1)$  expected time
- Requires  $O(n \log(M))$  bits of space.
  - $O(n)$  buckets
  - $O(n)$  items with  $\log(M)$  bits per item
  - $O(\log(M))$  to store the hash function

That's it for data structures  
(for now)

Now we can use these going forward!
